

# Types of Controllers

## Basic Controller

- This is the most common controller that is basically a class that extends the built-in `Controller` class.
- It has no methods in it when you generate it from the terminal.

## Single Action Controller

- Just as the name suggests, the single action controller only has a single method.
- For example, you can use it to display blog details, user profile etc.

## Resource Controller

- This type of controller is used to create resources.
- It comes with methods that correspond to the `GET`, `POST`, `PUT`, and `DELETE` HTTP verbs.
- Resource controllers can easily be bound to routes using a single name

## API Controller

- This type of controller is very similar to the resource controller except that the methods for displaying forms do not exist in the API Controller.
